

TEACHING

Anyone, anywhere, can learn to restore living soil.

A mentor teaching on working land.

From curiosity through to professional practice. Everyone starts with the Foundation Courses, and where you go next depends on whether you want to apply your skills to your own land or help others improve their soils.

Foundation Courses

You'll learn the science of the soil food web, the organisms and their roles, use of a microscope for biological analyses and how biological amendments are made and applied. They are online, self-paced, take about 150 hours to complete, and are a prerequisite to any Advanced Program.

Advanced Programs

Learn the practical application of the theory you learned in the Foundation Courses through mentor-led Advanced Programs on Soil Microscopy, BioComplete™ Compost Production, Biological Liquid Amendments and Field Trial.

Accelerator Workshops

The Advanced Programs as a group on working land, the whole method at once. Held periodically with a host partner. Dates on the school site.

Where it leads

All four Advanced Programs carry the Soil Food Web Consultant title; Soil Microscopy alone, the Lab Technician title. Prices at school.soilfoodweb.com

Apply for a scholarship

Scholarships prioritize applicants in under-resourced regions.

COMMUNITY

A global community makes this work outlast any one of us.

A workshop group around a finished compost pile.

Join the free community

Recordings, live discussion and your questions answered. Free, and open to anyone.

Dr. Ingham taught this so it could be passed on, and it was. Soil Regenerators on six continents teach their neighbors, run their own trials, and restore land farm by farm. They trade results, work through problems together and answer each other's questions, which is how a method outlives the person who found it. She gave this movement its science; the community keeps it alive, and there is a way in for anyone.

Soil Food Web
Foundation

A 501(c)(3) nonprofit

The soil beneath our farms and forests is alive.

A web of bacteria, fungi, protozoa, nematodes and microarthropods feeds plants, builds soil, stores carbon and cleans water *when it is intact*.

For forty-five years, Dr. Elaine Ingham mapped the Soil Food Web and taught the world to restore it. We carry her legacy forward: showing **what** is possible, teaching **how** to partner with life in the soil, researching **why** things work or do not, and getting dirty through **direct action** on working land. Living soil is the solution, and it is beneath your feet.

Feeding humanity.
Restoring the living world.

OUR STORY

It began with one scientist looking closer.

Dr. Elaine Ingham at the microscope.

The Soil Food Web Foundation was established in October 2025 to carry forward the life's work of Dr. Elaine Ingham, the pioneering scientist whose research transformed our understanding of soil biology and its central role in food production, ecosystem health, and planetary regeneration.

She passed away in February 2026, and the work she started continues through the Foundation, the school that is a part of it, and Soil Food Web practitioners in more than 132 countries, who are helping to restore the world's soils.

Examine Dr. Ingham's publications here: sfw.one/publications

WHY THIS MATTERS FOR CLIMATE

Soil carbon sequestration is widely recognized as a part of the solution to climate change impacts. Plants pull carbon from the air and invest much of it in the soil, where it is built into microbial bodies, aggregates and complex fungal networks. A biological approach to soil management reduces equipment emissions, reduces fertilizer and irrigation needs and creates more nutritious crops. Regenerating the world's soils using the Soil Food Web Approach can improve atmospheric carbon levels. Be part of the soil-ution!

RESEARCH

The science is open, and anyone can test it.

Soil samples beside the microscope.

Forty-five years of soil biology research, practiced by graduates in more than 132 countries on six continents.

What we test before we recommend

Measurable. Every recommendation starts with a count, not a guess.

Diagnostic first. We look at your soil before we suggest anything.

Compatible. No need to tear up what you have.

Each mechanism we teach is established soil biology. How much of any one benefit a field sees depends on climate, crop, starting condition and management. We publish results by site, with the person and the year, and say what one site cannot prove.

Her publications and the wider research, item by item: sfw.one/publications

PRACTICE

Growers are already doing this, at every scale.

Agroecology plots at Rancho Cacachilas.

The biology is universal; the practice is local. Every result we publish names the grower who got it and the year they did.

Nick Padwick farms four thousand acres in Norfolk, England. Roberto Silva works a hundred and forty in Piura, Peru. Jenn Sirp grows on a quarter acre in California. They film the work themselves and publish what changed, so nobody has to take our word for it.

The scale runs from that quarter acre to ten thousand acres of corn and soy in Illinois, and a public park on Governors Island in New York. The steps are the same at every size: look at the biology under a microscope, add what is missing, and measure again.

We partner with growers to trial the approach where they farm, and to document what happens when they do.

Find a trained professional near you

Consultants and lab technicians who finished the assessed programs are listed in our own directory.

Watch the case studies

Growers filming their own soil, crop by crop and climate by climate. Start with one that looks like yours.
